, and why is the software stack seeing such widespread interest and deeper dive.

Intro to the ELK Stack

What is the ELK Stack?

The ELK Stack is a collection of three open-source products — [Elasticsearch](#), [Logstash](#), and [Kibana](#) — all developed, managed and maintained by [Elastic](#). Elasticsearch is a NoSQL database that is based on the Lucene search engine. Logstash is a log pipeline tool that accents inputs from various sources, executes different transformations, and exports the

then presents the data in visualizations that provide actionable insights into one's environment.

Why is ELK So Popular?

The ELK Stack is popular because it fulfills a need in the log analytics space. Splunk's enterprise software has long been the market leader, but its numerous functionalities are increasingly not worth the expensive price — especially for smaller companies such as SaaS businesses and tech startups.

Why is Log Analysis Becoming More Important?

As infrastructures move to public clouds such as [Amazon Web Services](#) and [Google Cloud](#), [public cloud security tools](#), and logging platforms are becoming more and more critical.

In virtualized environments, performance isolation is extremely difficult to reach — especially when systems are heavily loaded. The performance of virtual machines in production fluctuates based on the specific loads, infrastructure servers, and the number of active users. As a result, reliability and node failures can become problems.

Modern log management tools can monitor all of these infrastructure issues as well as process logs, [NGINX](#) and [IIS](#) server logs for [technical SEO](#) and web traffic analysis, application logs, and [ELB and S3 logs on AWS](#).

In all of these contexts, DevOps engineers, system administrators, site reliability engineers, and developers can all use logs to make better decisions that are data-informed (and not, as [Facebook's Adam Mosseri says](#), data-driven). After all, “big data analytics” is increasingly important for a number of reasons — particularly when it comes to the cloud.

the ELK Stack is most commonly used for centralized logging. Installation and maintenance of a production-grade ELK Stack require a lot of time and many additional products. More information on installing and configuring the ELK Stack is provided in another section of this guide.

Architecture

The components in the ELK Stack were designed to interact and play nicely with each other, so you don't need much extra configuration. However, how you end up constructing your ELK Stack depends on the environment and specific use case in question. For a typical production environment, the classic architecture will look as follows:

To perform the steps below, we set up a single AWS Ubuntu 16.04 machine on an m4.large instance using its local storage. We started an EC2 instance in the public subnet of a VPC, and then we set up the security group (firewall) to enable access from anywhere using SSH and TCP 5601 (Kibana). Finally, we added a new elastic IP address and associated it with our running instance in order to connect to the internet.

What is Logstash?

In the ELK Stack ([Elasticsearch](#), [Logstash](#) and [Kibana](#)), the crucial task of parsing data is given to the “L” in the stack – Logstash.

Logstash started out as an open source tool developed to handle the streaming of a large amount of log data from multiple sources. After being incorporated into the ELK Stack, it

Inputs used are: file, beats, syslog, http, tcp, udp, stdin, but you can use a number of other sources.

Logstash has a number of extremely powerful filter plugins that enable you to enrich, parse, and transform logs. It's the power of these filters that makes Logstash a very powerful tool for parsing log data.

Filters are used with conditional statements to perform an action if a specific condition is met.

Outputs used are: grok, date, mutate, drop. You can read more about [Logstash Filter Plugins](#).

Output plugins

As with the inputs, Logstash supports a number of output plugins that enable you to push your data to various locations, services, and technologies. You can store events using outputs such as File, CSV, and S3, convert them into messages with RabbitMQ and SQS, or

Logstash pitfalls

As implied above, Logstash suffers from some inherent issues that are related to its design. Logstash requires JVM to run, and this dependency coupled with the implementation in Ruby became the root cause of significant memory consumption, especially when multiple pipelines and advanced filtering are involved.

Kibana searches cheat sheet

Below is a list of some tips and best practices for using the above-mentioned search types:

- Use free-text searches for quickly searching for a specific string. Use double quotes ("string") to look for an exact match.

brackets [], this means that the results are inclusive. If you use {}, this means exclusive.

statements (e.g. AND, OR, TO) within a search, use capital letters. Example: [400 TO 500]

define negative terms.

[400 TO 500] AND NOT response:404

are useful for searching terms within a specific character proximity. Example: search for all the terms that are within two changes from [categovi]. Proximity of resources – use wisely!

- Field level search for non analyzed fields work differently than free text search.
Example: If the field value is Error – searching for field:*rror will not return the right answer.
- If you don't specify a logical operator, the default one is OR.
Example: searching for Error Exception will run a search for Error OR Exception
- Using leading wildcards is a very expensive query and should be avoided when possible.

of open source log shippers that act as agents installed on the server environment for collecting logs or metrics. Written in Go, these beats had to be lightweight in nature — they leave a small installation footprint, efficient, and function with no dependencies.

The different beats vary — log files in the case of Filebeat, network data in the case of Packetbeat, server metrics in the case of Metricbeat, and so forth. In addition to the beats developed and supported by Elastic, there is also a growing list of beats developed and contributed by the community.

Once collected, you can configure your beat to ship the data either directly into Elasticsearch or to Logstash for additional processing.

The recommended method to ensure a resilient data pipeline is to place a buffer in front of the entry point for all log events that are shipped to your system. It will buffer the events until the downstream components have enough resources to index.

1/Elasticsearch Exceptions

trying to index logs in Elasticsearch that cannot fit into the mapped mapping.

For example, let's say you have a log entry that looks like this:

```

But later, your system generates a similar log that looks as follows:

change is required, just change the index according to the type of log.

2. Ensure that Logstash is consistently fed with information and monitor Elasticsearch exceptions to ensure that logs are not shipped in the wrong formats. Using mapping that is fixed and less dynamic is probably the only solid solution here (that doesn't require you to start coding).

At Logz.io, we solve this problem by building a pipeline to handle mapping exceptions that eventually index these documents in manners that don't collide with existing mapping.

datacenter — we recommend having a cluster of Elasticsearch nodes that run in different availability zones, or in different segments of a data center, to ensure high availability.

Let's take a look at some of the components required for a scalable ELK deployment.

Placing a buffer in front of your indexing mechanism is critical to ELK. It could be mapping conflicts, upgrade issues, hardware issues, or the volume of logs. Whatever the cause you need an overflow buffer, and here Kafka comes into the picture.

Logs that are to be indexed, Kafka must persist your logs in at least 2 replicas to retain your data (even if it was consumed already by Logstash) for at least 1 day.

When planning for the local storage available to Kafka, as well as the network bandwidth, remember to take into account huge spikes in traffic (up to 10 times of times more than “normal”), as these are the cases where you need the most.

Another consideration is the power you will have to dedicate to fixing issues in your Kafka cluster, including the retention capacity in Kafka.

Another important consideration is the ZooKeeper management cluster – it has its own requirements. Do not overlook the disk performance requirements for ZooKeeper, as well as the availability of that cluster. Use a three or five node cluster, spread across multiple racks/availability zones (but not regions).

When considering consumption from Kafka and indexing you should consider what level of parallelism you need to implement (after all, Logstash is not very fast). This is important to understand the consumption paradigm and plan the number of partitions you are using in your Kafka topics accordingly.

Logstash instances to run is an art unto itself and the answer depends on factors: volume of data, number of pipelines, size of your Elasticsearch cluster, expected latency — to name just a few.

Indexing mechanism with different scalable workers. When a queue is full, you need additional workers to read into Elasticsearch.

To speed up the number of Logstash instances required, run each one of them on a separate machine (VS). This comes at a cost due to data transfer but will guarantee a consistent pipeline.

Separate Logstash and Elasticsearch by using different machines for them. Since they both run as JVMs and consume large amounts of memory, it is not possible to run on the same machine effectively.

But it is recommended allocating a maximum of 30 GB or half of the available memory for Logstash. In some scenarios, however, making room for other processes is also a good best practice.

Elasticsearch cluster

Elasticsearch is composed of a number of different node types, two of which are the most important: the master nodes and the data nodes. The master nodes are responsible for cluster management while the data nodes, as the name suggests, are in charge of the data (read more about setting up an Elasticsearch cluster [here](#)).

Run in Different AZs (But Not in Different Regions)

We recommend having your Elasticsearch nodes run in different availability zones or in different segments of a data center to ensure high availability. This can be done through an Elasticsearch configuration that allows you to configure every document to be replicated

As with Logstash, the resulting costs resulting from this kind of replication are quite steep due to data transfer.

As your data may contain sensitive data, it is crucial to protect who can see it access to specific dashboards, visualizations, or data inside your Elasticsearch. There is no simple way to do this in the ELK Stack.

One way to do this is to use an nginx reverse proxy to access your Kibana dashboard, which requires a configuration that requires those who want to access the dashboard to provide a username and password. This quickly blocks access to your Kibana console.

Another way to do this is to use a security solution that allows you to set up roles and permissions. This is not out-of-the-box within open source ELK. There are some open source solutions that can help (e.g. SearchGuard) or you can use Elastic's X-Pack and build the security from Elasticsearch up the stack. At Logz.io, we take a different approach that allows for role-based access.

Last but not least, be careful when exposing Elasticsearch because it is very susceptible to attacks. There are some basic steps to take that will help you secure your Elasticsearch

apply the relevant parsing abilities to Logstash — which has proven to be quite a challenge, particularly when it comes to building groks, debugging them, and actually parsing logs to have the relevant fields for Elasticsearch and Kibana.

At the end of the day, it is very easy to make mistakes using Logstash, which is why you should carefully test and maintain all of your log configurations by means of version

As you may get started using nginx and MySQL, you may incorporate what you grow that result in large and hard-to-manage log files. The Internet has a lot of solutions around this topic, but trial and error are the norm with open source tools before using them in production.

Maintainability comes into play with excess indices. Depending on how much data, you need to have a process set up that will automatically delete old data. Otherwise, you will be left with too much data and your Elasticsearch will experience data loss.

When deleting, you can use Elasticsearch Curator to delete indices. We have a cron job that automatically spawns Curator with the relevant configuration to delete any old indices, ensuring you don't end up holding too much data. It's also possible to save logs to S3 in a bucket for compliance, so you want to be sure

to have a copy of the logs in their original format.

Index mapping

Elasticsearch, create an index, and feed it with JSON documents without a mapping. Elasticsearch will then iterate over each indexed field of the JSON document, and create a respective mapping. While this may seem ideal, mappings are not always accurate. If, for example, the wrong field type is used, errors will pop up.

You should define mappings, especially in production-line environments. To test, index a few documents, let Elasticsearch guess the field, and then retrieve the mappings with `GET /index_name/doc_type/_mapping`. You can then take your own hands and make any appropriate changes that you see fit without a mapping.

Index your first document like this:

```
1 {  
2  
3   "action": "Some action",  
4  
5   "payload": "2016-01-20"  
6  
7 }
```

Elasticsearch will automatically map the “payload” field as a date field

By default, the first cluster that Elasticsearch starts is called `elasticsearch`. If you are unsure about how to change a configuration, it's best to stick to the default configuration. However, it is a good practice to rename your production cluster to prevent unwanted nodes from joining your cluster.

Below is an example of how you might want to rename your cluster and nodes:

- Common Pitfalls	
- Use Cases	plugins with their own options and syntax instructions, differently named files, files that tend to become complex and difficult to understand
- Integrations	just some of the reasons why Logstash configuration files are the bane of the DevOps engineer.
- Additional Resources	

As a rule of the thumb, try and keep your Logstash configuration file as simple as possible. This also affects performance. Use only the [plugins](#) you are sure you need. This is especially true of the various filter plugins which tend to add up necessarily.

If possible — test and verify your configurations before starting Logstash in production. If you're running Logstash from the command line use the `--config.test` and `--exit` parameter

Recent versions of Logstash and the ELK Stack have improved this inherent weakness.

Using Filebeat and/or Elasticsearch Ingest Node, some of the processing can be outsourced to the other components in the stack. You can also make use of monitoring APIs to identify bottlenecks and problematic processing.

By default, the key-value filter will extract every key=value pattern in the source field. However, the downside is that you don't have control over the keys and values that are created when you let it work automatically, out-of-the-box with the default configuration. It may create many keys and values with an undesired structure, and even malformed keys that make the output unpredictable. If this happens, Elasticsearch may fail to index the resulting document and parse irrelevant information.

Defining an index pattern

There's little use for of an analysis tool if there is no data for it to analyze. If you have no data indexed in Elasticsearch or have not defined the correct index pattern for Kibana to work with, your work cannot start.

As the message reads, Kibana simply cannot connect to an Elasticsearch instance. There are some simple reasons for this — Elasticsearch may not be running, or Kibana might be configured to look for an Elasticsearch instance on a wrong host and port.

As implied in the opening statement above, some Kibana searches are going to crash Elasticsearch in certain circumstances.

For example, using a leading wildcard search on a large dataset has the potential of crashing your browser. I should, therefore, be avoided.

Filebeat is an extremely lightweight shipper with a small footprint, and while it is extremely rare to find complaints about Filebeat, there are some cases where you might run into high CPU usage.

One factor that affects the amount of computation power used is the scanning frequency

Summing it up

The ELK Stack is a fantastic piece of software with some known and some less-known weak spots.

The good news is that all of the issues listed above can be easily mitigated and avoided as described. The bad news is that there are additional pitfalls that have not been detailed

affects almost all the steps implemented along the way — where and how to install the stack, how to configure your Elasticsearch cluster and which resources to allocate to it, how to build data pipelines, how to secure the installation — the list is endless.

So, what are you going to be using ELK for?

being in handy during a crisis. The first place one looks at when an error occurs is in your error logs and exceptions. Yet, logs come in handy much earlier in the development cycle.

Observability is in log-driven development, where logging starts from the very first line of code. When an application is subsequently instrumented throughout the entire application, every line of code into your code adds a measure of observability into your system. This makes logs in handy when troubleshooting issues.

When developing a monolith or microservices, the ELK Stack comes into the picture. It provides means for developers to correlate, identify and troubleshoot errors in a centralized place, preferably in testing or staging, and before the code goes into production. By using a variety of different appenders, frameworks, libraries and shippers, log messages are pushed into the ELK Stack for centralized management and analysis.

Once in production, Kibana dashboards are used for monitoring the general health of applications and specific services. Should an issue take place, and if logging was instrumented in a structured way, having all the log data in one centralized location helps make analysis and troubleshooting a more efficient and speedy process.

considerations: how to access each machine, how to collect the data, how to add context to the data and process it, where to store the data and how long to store it for, how to analyze the data, how to secure the data and how to back it up.

The ELK Stack helps by providing organizations with the means to tackle these questions by providing an almost all-in-one solution. Beats can be deployed on machines to act as

data to Logstash instances. Logstash can be configured to process it before indexing the data in Elasticsearch. Kibana is then used to visualize the data, detect anomalies, perform root cause analysis, and build dashboards.

While Elasticsearch was initially designed for full-text search and is now commonly being used for metrics analysis as well. Monitoring performance of your architecture is key for gaining visibility into operations. This can be done using 3rd party auditing or monitoring agents or by using the available beats (e.g. Metricbeat, Packetbeat) and Kibana now ships with visualizations to help analyze time series (Timelion, Visual Builder).

Compliance

Security has been crucial for organizations. Yet over the past few years, because of both an increase in the frequency of attacks and compliance requirements (HIPAA, PCI, SOC, FISMA, etc.), employing security mechanisms and standards has become a top priority.

Because log data contains a wealth of valuable information on what is actually happening in real time within running processes, it should come as little surprise that security is fast becoming a strong use case for the ELK Stack.

1.Anti-DDoS

Once a DDoS attack is mounted, time is of the essence. Quick identification is key to minimizing the damage, and that's where log monitoring comes into the picture. Logs contain the raw footprint generated by running processes and thus offer a wealth of information about what is happening in real time.

- Organizations can build a system that aggregates data from the environment (web server, databases, firewalls, etc.), process the data, and visualizes the data in powerful monitoring dashboards.
- SIEM is an enterprise security management that seeks to provide a holistic view of an organization's IT security. The main purpose of SIEM is to provide a comprehensive view of your IT security. The SIEM approach includes a dashboard that allows you to identify activity, trends, and patterns easily. If implemented correctly, SIEM can prevent legitimate threats by identifying them early, reducing the risk of data breaches, providing compliance reports, and supporting incident-response efforts.

Log monitoring is instrumental in [achieving SIEM](#). Take an AWS-based environment as an example. Organizations using AWS services have a large amount of auditing and logging tools that generate log data, auditing information and details on changes made to the configuration of the service. These distributed data sources can be tapped and used together to give a good and centralized security overview of the stack.

databases, supply chains, personnel records, manufacturing data, sales and marketing campaigns, and more. The data itself might be stored in internal data warehouses, private clouds or public clouds, and the engineering involved in extracting and processing the data (ETL) has given rise to a number of technologies, both proprietary and open source. As with the previous use cases outlined here, the ELK Stack comes in handy for pulling data from these varied data sources into one centralized location for analysis. For example,

Over the last few years, we have written a large number of articles describing different ways to integrate the ELK Stack with different systems, applications and platforms. The method varies from a data source to data source — it could be a Docker container, Filebeat or Logstash, or even a cloud provider like AWS and so forth. Just take your pick.
